Endophytic fungi belonging to the Balansieae tribe were first hypothesized to cause poor livestock performance in 1977 and, in 1980, the association was validated. The fungi were extensively studied and classified according to morphology, their life cycles examined to determine methods to eliminate the fungi in grasses, and practical methods developed for livestock producers to eliminate endophyte-infected plants from pastures and establish endophyte-free plants. Hindsight illustrates how primitive was our understanding of the associations between endophyte, grass plant, and animal. The plant-endophyte associations, thought to be rare cases, have now been identified in grasses that are adapted from tropical to nearly arctic, and from marshland to desert climatic regimes. In the two decades that have passed since the first endophyte-plant-animal association was made, the scientific community has re-classified the endophytic fungi twice (now the genus *Neotyphodium*), the systematics and ecological role of endophytes have been more clearly defined, endophytes and grasses are now generally accepted as mutualistic symbionts, the chemistry of toxins and their functions defined, beneficial effects of endophytes on plants identified, and commercial ventures have emerged based upon endophyte research in the turfgrass and livestock industries. This item ships from multiple locations. Your book may arrive from Roseburg, OR, La Vergne, TN. Paperback.
